$\gamma$ spectroscopy

Recording a $\beta$ spectrum with a scintillation counter

Description from CASSY Lab 2

For loading examples and settings, please use the CASSY Lab 2 help.
Recording a β spectrum using a scintillation counter

Safety note
When handling radioactive preparations, in addition to the radiation protection regulations, state-specific requirements and the regulations of the educational authorities are also to be observed, e.g. in the Federal Republic of Germany at the very least the radiation protection regulations (StrlSchV - Strahlenschutzverordnung) and the directives on safety during school lessons. The preparations used in this experiment are type approved according to StrlSchV (2001) or they are below the exemption limit and do not require approval. For this reason handling without express permission is possible.

Since the used preparations produce ionizing radiation, the following safety rules must nevertheless be kept to:

- Prevent access to the preparations by unauthorized persons.
- Before using the preparations make sure that they are intact.
- For the purpose of shielding, keep the preparations in their safety container.
- To ensure minimum exposure time and minimum activity, take the preparations out of the safety container only as long as is necessary for carrying out the experiment.
- To ensure maximum distance, hold the preparations only at the upper end of the metal holder.

Experiment description
The β spectrum of Sr-90 is recorded with a scintillation counter. The energy loss per path length dE/dx of the β particles in aluminum is measured.

CASSY Lab 2

1 Set of absorbers and targets 559 94
1 Scintillation counter 559 901
1 Detector output stage 559 912
1 High-voltage power supply 1.5 kV 521 68
1 Scintillator screening 559 89
1 Socket for scintillator screening 559 891
1 Stand rod, 47 cm 300 42
1 Leybold multiclammp 301 01
1 Universal clamp, 0...80 mm 666 555
1 PC with Windows XP/Vista/7/8

Experiment setup (see drawing)
The output stage of the scintillation counter is connected to the MCA box and to the high-voltage power supply. The scintillation counter is mounted in the socket from above with the lead screening. The acrylic glass tube is put over the scintillation counter within the lead screening. The preparation is place a few centimeters above the scintillation counter with stand material. The absorber plates are laid on the acrylic glass tube so that they are located between the detector and the preparation.

Carrying out the experiment

Load settings
- Mount the Sr-90 preparation, and record the spectrum with . Set the high voltage so that the spectrum is not cut off on the right side.
- For the energy calibration, mount the Na-22 preparation, and calibrate the energy axis with the 511 keV and the 1275 keV line. The Sr-90 spectrum extends to approx. 2000 keV.
- It is recommendable to determine the background without preparation.
- Mount the Sr-90 preparation once more, and see to it that there is enough space for the absorbers.
- One after another record the spectra without absorber, with a 0.5 mm thick aluminum absorber, 1 mm aluminum, and so on up to 3 mm aluminum.

Evaluation
The aluminum absorber reduces the maximum energy of the electron reaching the detector. The highest energy of each Sr-90 spectrum at which electrons are detected is determined. These energies are compiled in a table together with the corresponding thickness of the absorber. The slope of the regression line gives the energy loss per path length dE/dx, which, in this case, amounts to about 400 – 450 keV/mm.
